The distribution of carbonate platforms and associated biota is considered to be an essential indicator of the tropical marine environment and biotic realm (Tethyan Realm) in the Cretaceous. Understanding shallow-marine carbonates and associated biota in the Northwest Pacific provides important clues for evaluating the paleobiogeographic and paleoenvironmental history in this region (Iba and Sano, 2007, 2008). However, the detailed lithology and paleontology of shallow-marine carbonates from the pre-Aptian Cretaceous of the Northwest Pacific are still poorly understood (Iba and Sano, 2007).

The Sanchu Cretaceous System is widely distributed along the axial part of the Chichibu Belt in the western Kanto Mountains (Fig. 1), and is referred to the Lower Cretaceous fore-arc basin fill sediments underlain unconformably by the Jurassic Accretionary wedge. We report a pre-Aptian Cretaceous (late Hantarian-Barronian) small-scale in situ shallow-marine carbonates and calcareous sandstone (total thickness is about 5.5 m with poor lateral continuity) in the lowermost part of the Ishido Formation of the Sanchu Cretaceous System exposed along the Otchi Creek, Gunma Prefecture, central Japan (Figs. 1, 2, and 3). These calcareous sediments lie above basal conglomerate belonging to the Ishido Formation (Figs. 3, 4), and contain abundant Mesogean taxa (e.g., hermatypic corals and orbitolinid foraminifers), “Tethyan non-rudist bivalves” (Neothamnus gigas and Rostellum sp.), and coated grains (Figs. 4, 5). These shallow-marine carbonates are characterized by 1) their small scale, typically several meters both in thickness and lateral continuity, and 2) being intercalated with siliciclastic sequences and containing abundant terrigenous clastics. These features illustrate one of the typical mode of occurrence of shallow-marine carbonates and the Tethyan biota in island arc and/or active-margin settings (Iba and Sano, 2007). The presence of shallow-marine carbonates and associated biota in the Ishido Formation, clearly indicates that this region belonged to the Tethyan Realm, and was subject to tropical climatic conditions at that time.
